1. Field of the Invention The present invention relates to a coating device and a method for forming a coating on a substrate. In particular, the present invention relates to an apparatus for forming a coating on a substrate and a method of forming a coating on the substrate with a uniform thickness. 2. Background Art A thin film forming apparatus is used to form a thin film on a substrate by a conventional method. With the thin film forming apparatus, a container is loaded with a liquid material and a substrate is placed on a platen. When the substrate is pressed against the platen, a specified amount of the liquid material is absorbed into the substrate through a nozzle in contact with the substrate. The liquid material absorbed into the substrate is retained with a bond at a dry region after forming the thin film. At this time, the liquid material is partially in contact with the substrate. The thin film forming apparatus controls the amount of the liquid material retained in the substrate. As an apparatus for forming a thin film, there are a spray gun, a nozzle, etc. The amount of the liquid material retained in the substrate is determined by a pressure of the fluid and an interval between spray portions. In some cases, thin film forming operation is performed on a substrate having a thickness of about several hundred micrometers. At this time, an amount of liquid material retained in the substrate is about several dozen milligrams to several hundred milligrams. In order to retain a desired amount of the liquid material, it is necessary to determine a pressure of the fluid and an interval between spray portions. In order to control the pressure of the fluid and the interval between spray portions, a pair of pinch rollers are used. The pinch rollers are located in a path of the fluid between a discharge port of the liquid material and the substrate. The pinch rollers pinch and adjust the amount of the fluid. The pinch rollers hold a space for adjustment of the amount of the fluid by pressing the pinch rollers against the substrate. In some cases, the pinch rollers are moved back and forth in a horizontal direction and a vertical direction, by a cam driven through a cam operation mechanism, to form a gap between the pinch rollers and the substrate. In this case, a gap between the pinch rollers and the substrate is about 100 micrometers to several hundred micrometers. Therefore, it is necessary to precisely control the movement distance of the pinch rollers. A conventional pinch roller is moved by a cam operation
